

CLUTCH

- A clutch is a machine member used for transmission of power between driving and driven shafts which has to be engaged and disengaged at will
- Clutch is a device to connect driving and driven shafts of a machine, where the driven shaft can be disconnected almost instantaneously from the driving shaft as desired by the operator or driver.

Clutches

Clutches

In a car, you need a clutch because the engine spins all the time, but the car's wheels do not. In order for a car to stop without killing the engine, the wheels need to be disconnected from the engine somehow. The clutch allows us to smoothly engage a spinning engine to a non-spinning transmission by controlling the slippage between them.

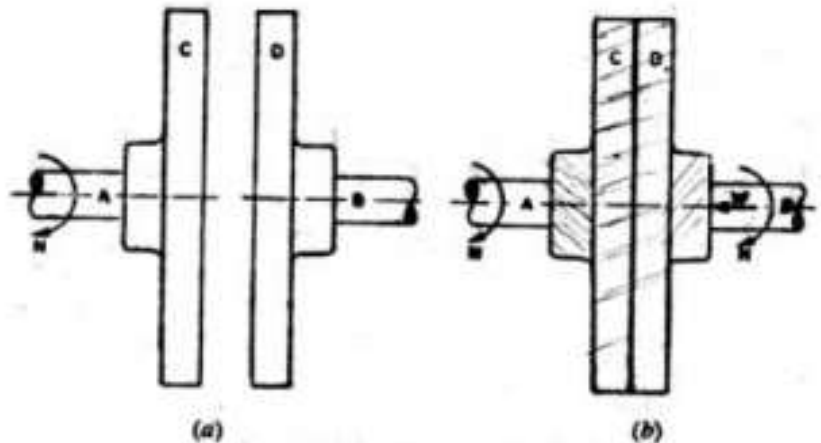

Types of clutch

- Positive clutch
- Friction clutch

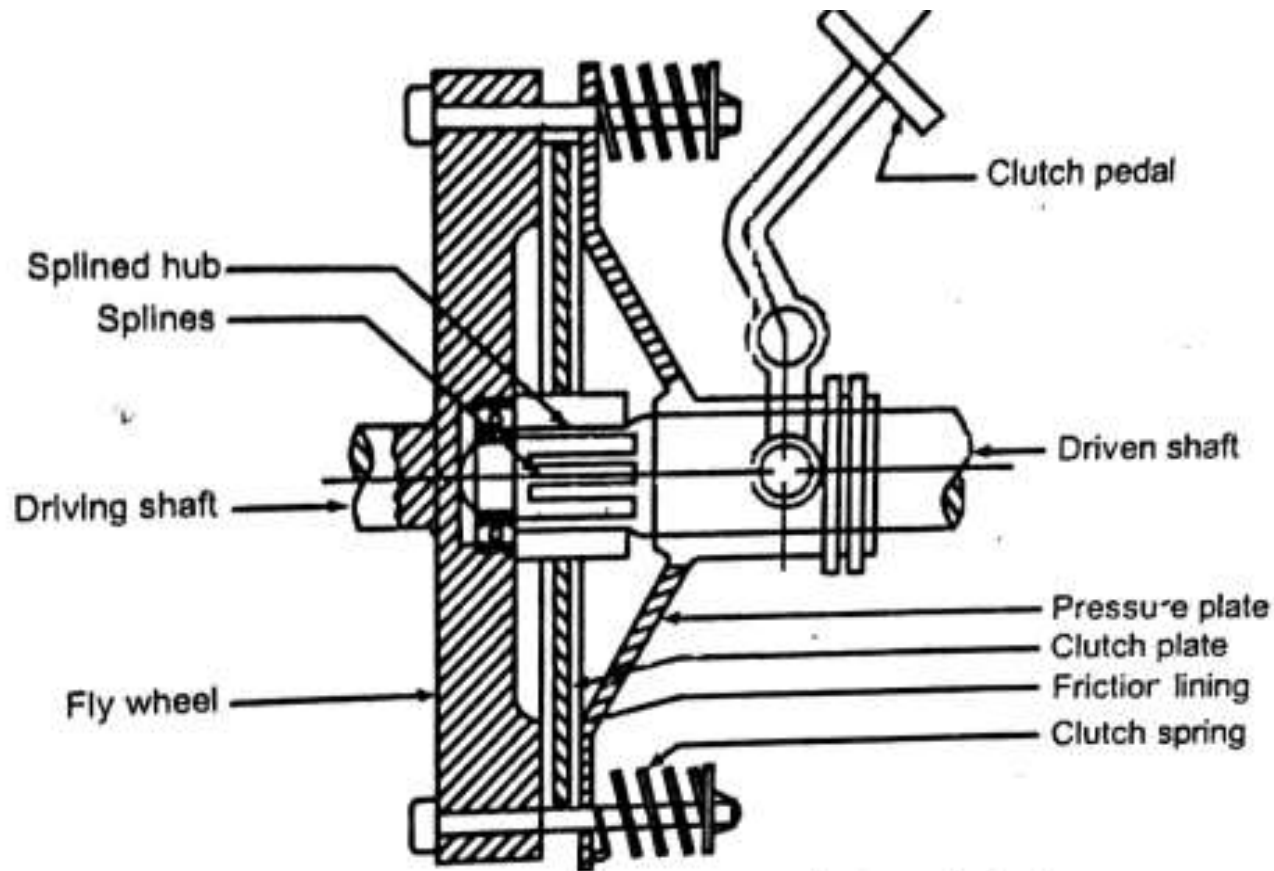

Types of Clutches

► *Single Plate Clutches (Friction Clutches)*

The friction clutches work on the fact that friction is caused when two rotating discs come into contact with each other. the clutch needs three parts. These are the engine flywheel, a friction disc called the clutch plate and a pressure plate.

Single Plate Clutch (Friction Clutches)

Types of Clutches

► *Multi Plate Clutches (Friction Clutches)*

The multi plate clutch is an extension of single plate type where the number of frictional and metal plates is increased.
